## LESSON 1

# *Composite Model of Loaded Flat Plate*

### What you will learn in this exercise

- 7 MSC/Patran's capabilities with Composites
- 8 Create a orthotropic material, a lamina and a layup
- 9 Postprocess calculations done on a composite model
- 10 The shortcomings in traditional composites calculations

## THE MODEL

We will model a 1x1 meter plate, we will use millimetres as length measurement.

The plate is 4 mm thick and is a laminate made up of 16 plies with equal thickness. The laminate is uniform on the plate. The plies have two orientations: 0 and 90 degrees, i.e. parallel to the plate edges.

The material properties of the lamina are:

E-modulus:  $E_{11} = 181000$  MPa,  $E_{22} = 10300$  MPa

Shear modulus:  $G_{12} = 7170$  MPa,  $G_{23} = 5000$  MPa,  $G_{13} = 7170$  MPa

Poisson Ratio: 0.28

Density:  $1.6E-09$  kg/mm<sup>3</sup>

The plate is fixed along one end and supported vertically in one of the other two corners.

The plate is loaded with a uniform pressure of 0.1k Pa, giving an total force acting on the plate of 100 Newtons.

We want to investigate the occurring stresses and maximum deflection of the plate.

MacNeal-Schwendler  
**Nordic AS**

Erling Wiig

*Laminate Modeler*  
*Course Exercises*

## **1 Open a new filebase using the default template database**

File, New...

New Database Name: enter "flatplate"

Ok

Ok

## **2 Create a plate 1 m square using units of Newton and Millimeter**

◆ Geometry

Action : Create

Object : Surface

Method : XYZ

Vector Coordinates List : enter "<1000 1000 0>"

Origin Coordinates List : enter "[0 0 0]"

Apply

MacNeal-Schwendler  
**Nordic AS**

Erling Wiig

*Laminate Modeler*  
*Course Exercises*

*This is all the geometry needed for this model.*

### 3 Create a mesh

◆ Finite Elements

Action : Create

Object : Mesh

Method : Surface

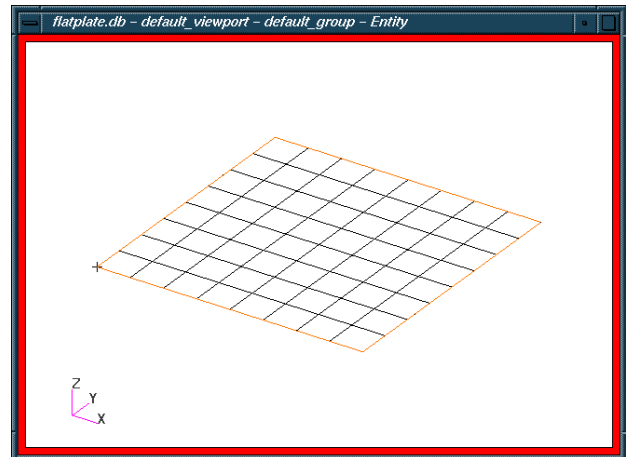

Global Edge Length : enter  
"125"

Element Topology : select  
Quad4

Mesher : select Isomesh

Surface List : pick Surface 1

Apply

### 4 Define loads and boundary conditions

◆ Loads/BCs

Action : Create

Object : Displacement

Method : Nodal

New Set Name : enter "Fixed Line"

Input Data ...

Translations <T1 T2 T3>: enter "<0,0,0>"

Ok

Select Application Region...

Application Region : pick Surface 1.4 (edge)

Add

Ok

Apply

Action : Create

Object : Displacement

Method : Nodal  
New Set Name : enter “Supported Point”  
Input Data ...  
Translations <T1 T2 T3> : enter “<,,0>”  
Ok  
Select Application Region...  
Application Region : pick Point 2  
Add  
Ok  
Apply

Action : Create  
Object : Pressure  
Method : Element Uniform  
New Set Name : enter “Pressure Load”  
Target Element Type : 2D  
Input Data ...  
Top Surf Pressure : enter “0.0001”  
Ok  
Select Application Region...  
Application Region : pick Surface 1  
Add  
Ok  
Apply

*Note the pressure 0.0001 which is in MegaPascals.*

*Until now this exercise has been quite straight forward, but the next step is to define the laminate.*

## 5 Define lamina material properties

*Now we input the orthotropic material properties valid for the lamina.*

### ◆ Materials

Action : Create

Object : 2d Orthotropic

Method : Manual Input

Material Name: enter “ud\_t300\_n5208”

Input Properties...

Constitutive Model: Linear Elastic

Elastic Modulus 11: enter “181000”

Elastic Modulus 22: enter “10300”

Poisson Ratio 12: enter “0.28”

Shear Modulus 12: enter “7170”

Shear Modulus 23: enter “5000”

Shear Modulus 13: enter “7170”

Density: enter “1.6E-09”

Apply

Cancel

*We will also use this material in later exercises, so a session file that makes this material is included in the work files for this course, named “materials.ses”.*

Property Name	Value
Elastic Modulus 11 =	181000
Elastic Modulus 22 =	10300
Poisson Ratio 12 =	0.28
Shear Modulus 12 =	7170
Shear Modulus 23 =	5000
Shear Modulus 13 =	7170
Density =	1.6E-9
Thermal Expan. Coeff 11 =	
Thermal Expan. Coeff 22 =	
Structural Damping Coeff =	
Reference Temperature =	

## **6 Define laminate properties**

*Now we build the laminate out of the lamina we just defined. Take notice of how the laminate is defined in the spreadsheet.*

Action : Create

Object : Composite

Method : Laminate

Material Name : enter "My first Laminate"

Text Entry Mode : Insert, Material Names

Enter "16(ud\_t300\_n5208)" in the input window

Press "Load Text Into Spreadsheet"

Text Entry Mode : Overwrite Thicknesses

Enter "16(0.25)" in the input window

Press "Load Text Into Spreadsheet"

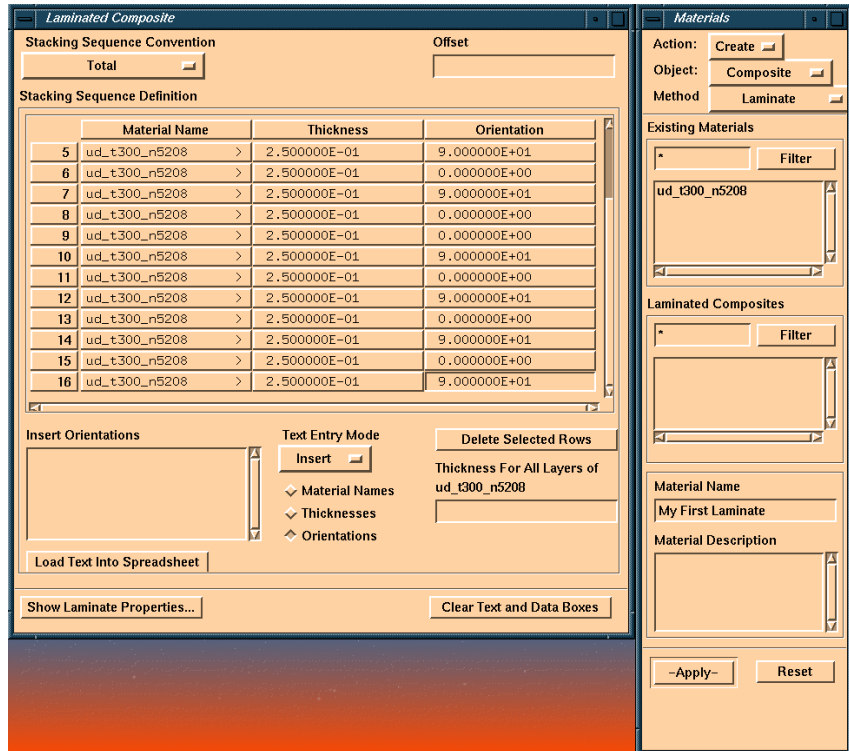

Text Entry Mode : Overwrite Orientations

Enter "4(90/0)" in the input window

Press "Load Text Into Spreadsheet"

Text Entry Mode : Overwrite Orientations

Enter "4(0/90)" in the input window

Press “Load Text Into Spreadsheet”

Apply

## 7 Define element properties

*The composite laminate can now be associated to the model.*

### ◆ Properties

Action : Create

Object : 2D

Type : Shell

Property name : enter “Shell Property”

Option 1: Laminate

Option 2 : Standard Formulation

Input Properties...

Material Name: select “My\_First\_Laminate” from list below

Material Orientation : Vector, Coord 0.1

Ok

Application Region : pick Surface 1

Add  
Apply

*Now we have related the fiber direction to the global coordinate x-axis. Half of our fibres are rotated 90 degrees related to this direction.*

## **8 Verify Laminate Directions**

*It is a good rule to check your model before an analysis is run, especially when dealing with laminates. Remember that layer 1 is at the bottom of the elements. First we need to check the element normals, to determine what direction is up.*

◆ Finite Elements

Action : Verify

Object : Element

Test: Normals

Display Control : Draw Normal Vectors

Apply

*Verify that all vectors are pointing in the positive z-axis direction*

◆ Properties

Action: Show

Existing Properties: Select “Orientation Angle”

Display Method: Select “Vector Plot”

Apply

*We now see the initial reference direction. Note that we cannot see the individual fibre directions. We can only check them in the laminate spreadsheet. You can also select to show the thickness, but this is of little interest in this case.*

## **9 Set up and run the analysis**

### ◆ Analysis

Action : Analyse

Object: Entire Model

Type : Full Run

Subcase Create ...

Available Subcases : select “Default”

Output Requests...

Form Type: Advanced

Output Requests: select “Stress”

Composite Plate Opt : Ply & Elem. Stresses

Modify

Ok

Apply

Cancel

Apply

*The analysis should run through in a few seconds time.*

MacNeal-Schwendler  
**Nordic AS**

Erling Wiig

*Laminate Modeler*  
*Course Exercises*

**10 Read in MSC/Nastran analysis results**

Action : Read Output2

Object : Result Entities

Method : Translate

Select Result File...

Selected Results File : pick “flatplate.op2”

Ok

Apply

## **10 View the Results**

*First we want to look at the stresses in one of the layers. For illustrations sake, we choose layer 12, and plot stresses in the x-direction.*

### ◆ Results

Select Result Case : pick “Default, Static Subcase”

Select Fringe Result : pick “Stress Tensor”

Position : select “Layer 12”

Close      *(the layer selection menu)*

Option : Maximum

Close

Quantity: select “X Component”

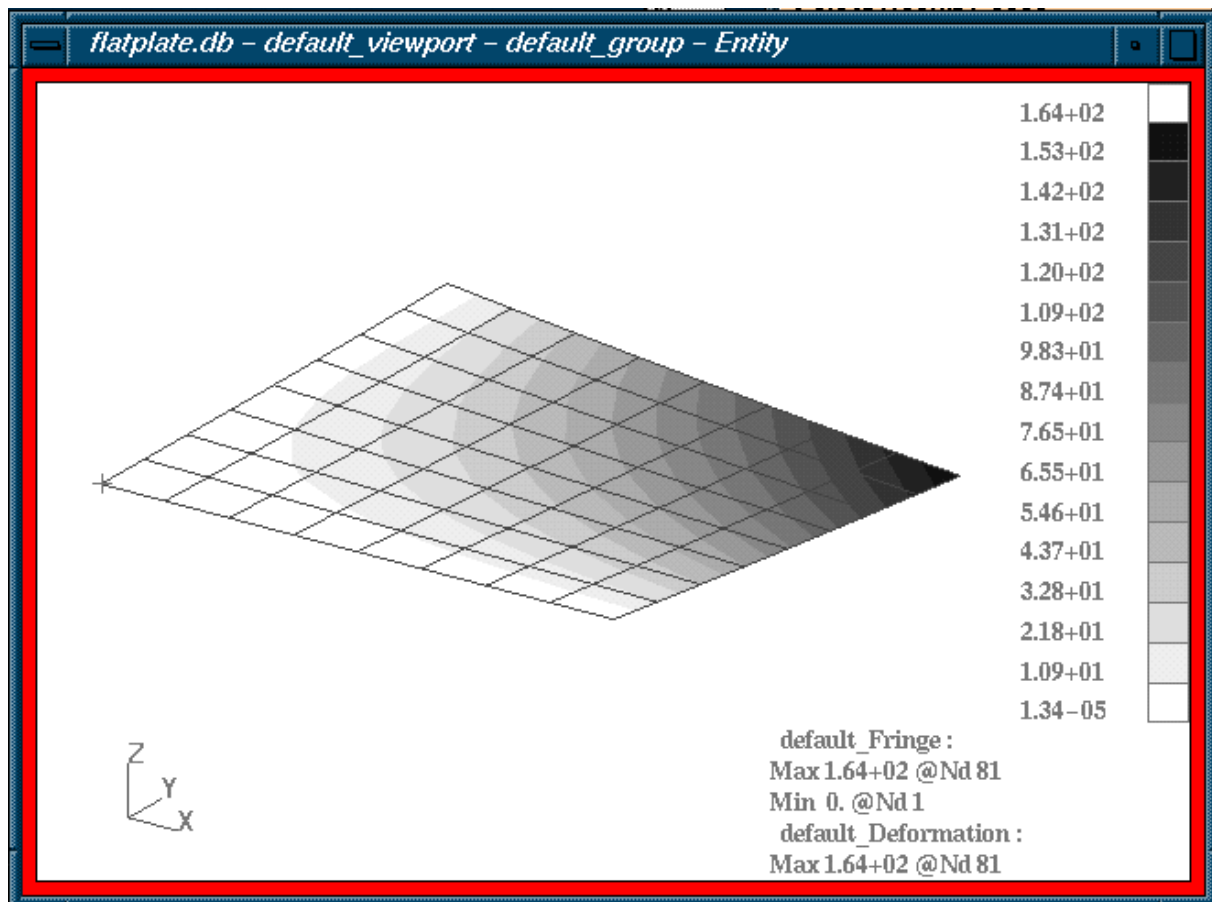

Select Deformation Result: select “Displacements, Translational”

Apply

We also want to investigate the deflection of the plate

Select Fringe Result : Displacements, Translational  
Apply

### 11 EXTRA, If time

*Another laminate builder tool is situated in the Utilities menu, Materials, Laminate Builder tool. Check it out.*

# LESSON 2

## *Failure Criteria for Flat Plate*

### What you will learn in this exercise

- 11 How to Define a Composite Failure Criterion
- 12 Set up a Margin of Safety analysis
- 13 Postprocess Margin of Safety results
- 14 Edit existing Composite

MacNeal-Schwendler  
**Nordic AS**

Erling Wiig

*Laminate Modeler*  
*Course Exercises*

## Additional Material information

Material allowables are needed for the Margin of Safety Analysis, the following values can be used for the material:

Tension Stress Limit 11	1500
Tension Stress Limit 22	40
Compress Stress Limit 11	1500
Compress Stress Limit 22	246
Shear Stress Limit	68
Interaction Term	-0.5
Bonding Shear Stress	50

## **1 Open the last exercise database**

File, Open...

Existing Database Name : select "flatplate.db"

Ok

## **2 Define Constitutive Failure Model**

◆ Materials

Action : Create

Object : 2d Orthotropic

Method : Manual Input

Material Name : select "ud\_t300\_n5208"

Constitutive Model : Failure

Failure Limits : Stress

Composite Failure Theory : Tsai-Wu

Tension Stress Limit 11 : enter "1500"

Tension Stress Limit 22 : enter "40"

Compress Stress Limit 11 : enter "1500"

Compress Stress Limit 22 : enter "246"

Shear Stress Limit :  
enter "68"  
Interaction Term :  
enter "-0.5"  
Bonding Shear Stress  
Limit : enter "50"  
Apply  
Cancel

### **3 Do the failure calculation**

Tools, LAMINATE MODELLER...

New Layup File...

Ok (Accept the default file name)

Action : Create

Object : LM\_Results

Method : Failure Calc

Select Loadcase : pick "1- Default"

Select Subcase : pick "1- Static Subcase"

Select Layered Result : pick "3.1- Stress Tensor"

Select Area : select "Elm 1:64"

Criterion : Tsai-Wu

Material Allowables...

Ok (accept default values)

Apply

*Take notice of that instead of defining the Constitutive Failure Model under the Material Menu in Patran, you could fill in the same values in the above menu in MSC/Laminate Modeler.*

*When hitting Apply, the calculation is done immediately and the results are put into the result database.*

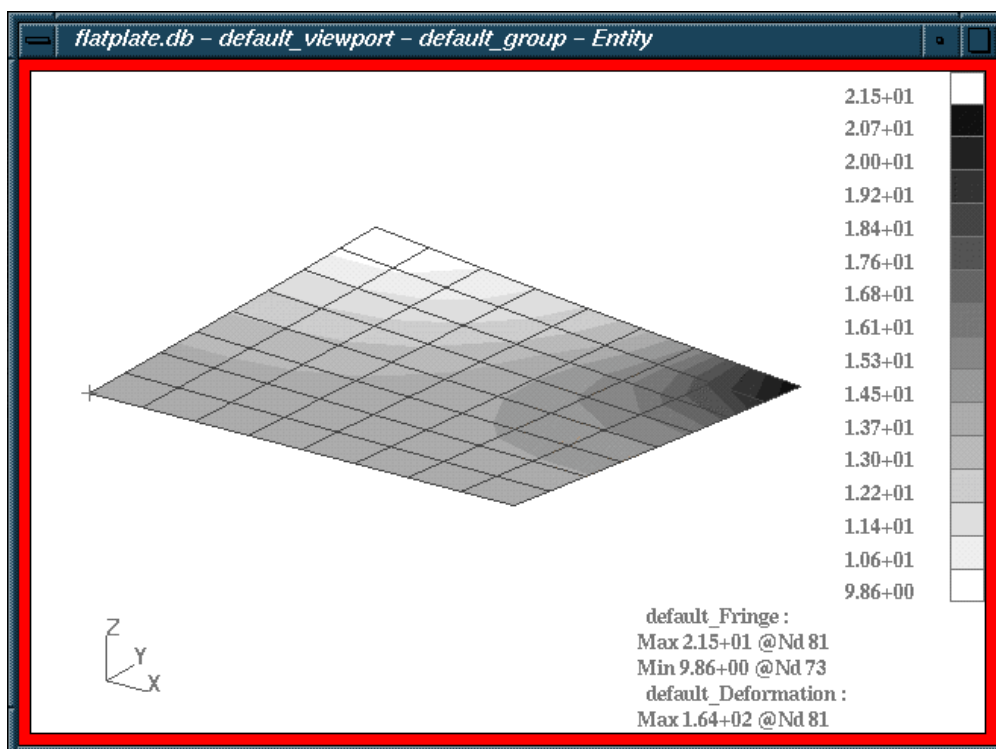

#### 4 View Failure Results

◆ Results

Select Result Cases : select “Default, Static Subcase”

Select Fringe Result : select “LM\_Marg\_Saf, ,....”

Apply

*We do have a factor of 10 in safety according to this*

#### 5 Alter Failure Model

*Now let's repeat step 3 and 4 with other failure models*

Tools, LAMINATE MODELLER...

Open Layup File...

Layup file Name: select “flatplate.Layup”

Ok

Action : Create

Object : LM\_Results

Method : Failure Calc

Select Loadcase : pick "1- Default"

Select Subcase : pick "1- Static Subcase"

Select Layered Result : pick "3.1- Stress Tensor"

Select Area : select "Elm 1:64"

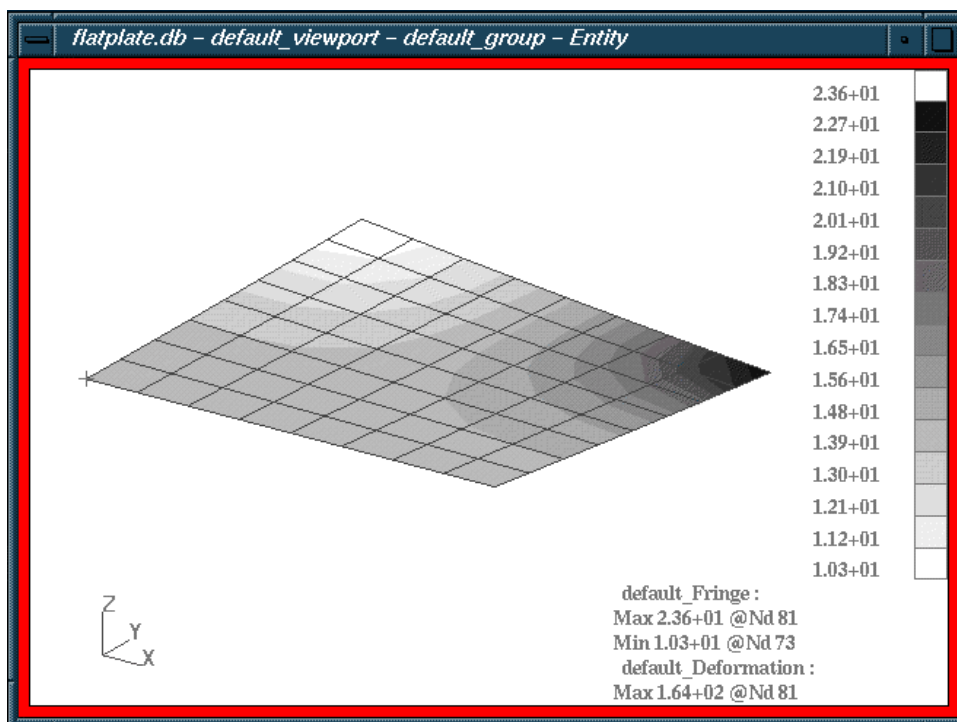

Criterion : Maximum

Material Allowables...

Ok (accept default values)

Name: maximum

Apply

MacNeal-Schwendler  
**Nordic AS**

Erling Wiig

*Laminate Modeler*  
*Course Exercises*

*The different theories should yield:*

<i>Maximum</i>	<i>10.3</i>
<i>Tsai-Wu</i>	<i>9.86</i>
<i>Hill</i>	<i>10.3</i>
<i>Hoffman</i>	<i>9.85</i>
<i>Hankinson</i>	<i>10.0</i>
<i>Cowin</i>	<i>10.0</i>

MacNeal-Schwendler  
**Nordic AS**

Erling Wiig

*Laminate Modeler*  
*Course Exercises*

## **6 Modify the laminate**

Try modifying your model to optimize its strength at the same time as we reduce its weight..

Suggestion: Delete ply number 15 and 16. Reorder the remaining plies as follows: 2 ( 45 / 90 / 0 / 45 / 90 / 0 / 45 ). Re-run the analysis. The new deflection is now down from 164 to 116 millimetres at the same time as we reduced its weight by 12.5%.

*If you have any questions, please do not hesitate to ask!*

MacNeal-Schwendler  
**Nordic AS**

Erling Wiig

*Laminate Modeler*  
*Course Exercises*

## LESSON 3

# *Making Plies and Layup on a Fairing Component*

### What you will learn

- 15 Make plies in Laminate Modeler
- 16 Make a layup in Laminate Modeler
- 17 Get some experience on a more realistic model

### **1 Make the geometry**

Open a new database fairing.db

Generate the geometry and finite elements by playing the session file  
“fairing\_geom.ses”

### **2 Apply the loads and boundary conditions**

Enter displacement restriction one  $\langle 0,0,0 \rangle$  on edge “Surface 7.3”

Enter displacement restriction two  $\langle 0,, \rangle$  on edge “Surface 7.1”

Create pressure load (2D) with Top pressure 0.1 on “Surface 1:6”

### **3 Enter the material properties**

Define the ply material properties by playing the session file  
“materials.ses”

Enter the Laminate Modeler and open a new layup file

Define the laminate modeler material from “ud\_t300\_n5208” with  
thickness 0.25, all other settings default.

### **4 Create the plies**

Set view angles to  $-100,-10,40$  (Viewing, Angles...)

Create a ply with

18 Application Region: Surface 1 3 2 7

19 Starting point: Node 75

20 Reference Direction: Along fairing, e.g. from Node 75 to Node  
108

21 Reference Angle: 0

Repeat for reference angle 45 degrees

Make the 8 next plies as follows, keep the starting point for all, see the below figure for the correct view angles.

Keep the starting point at node 75

<u>Ply #</u>	<u>Reference Angle</u>	<u>Application Region</u>	<u>View Vectors</u>
3	0	Surface 7 5 6 4	(-100,0,20)
4	45	“	
5	0	Surface 3 5	(80,-5,20)
6	45	“	
7	0	Surface 2 3 5 6	
	1.8	45	“
9	0	Surface 1 2 3 4 5 6	
10	45	”	

### **5 Create the layup**

Define the layup by stacking the plies as shown in the table below:

<u>Number</u>	<u>Ply stacking sequence</u>
1-8	1 / 2 / 1 / 2 / 1 / 2 / 1 / 2
9-16	3 / 4 / 3 / 4 / 3 / 4 / 3 / 4
17-24	5 / 6 / 5 / 6 / 5 / 6 / 5 / 6
25-32	7 / 8 / 7 / 8 / 7 / 8 / 7 / 8
33-40	9 / 10 / 9 / 10 / 9 / 10 / 9 / 10

You should now have 40 layers of plies

Use no offset, standard element type, and default tolerance

*When hitting apply, the program informs you that it created 8 laminate materials and 21 property regions.*

## **6 Check you model before solving**

Check the plies (fiber direction and application region) using the Laminate Modeler

Action: Show

Object: Ply

Method: Graphics

LM\_Ply\_Data: *Select one ply*

Apply

Action: Show

Object: LM\_Layup

Method: Exploded

Select LM\_Plys: *Select several plies or even all*

Apply

## **7 Create the analysis input deck**

Remember to request ply stress as output

## **8 Analyse and read the results**

Run the analysis and read the result

Verify that the laminate materials and properties have been created

MacNeal-Schwendler  
**Nordic AS**

Erling Wiig

*Laminate Modeler*  
*Course Exercises*

## **9 Postprocess the results**

Take a look at the deformations, the different layer stresses etc.

*If you have any difficulty with this exercise, examine or play the session file "fairing.ses" after opening a new database.*

## LESSON 4

# *Draping a Doubly Curved Surface*

MacNeal-Schwendler  
**Nordic AS**

Erling Wiig

*Laminate Modeler*  
*Course Exercises*

What you will learn from this exercise

- 22 How to make a drape
- 23 How different inputs, such as starting point and reference angle, affect shear
- 24 What is meant by step length

### **4.1 Make the model**

Open a new database called “Drapeintro.db”

Play session file “drapeintro\_geom.ses” to create geometry and mesh

### **2 Create the materials**

Play session file “materials.ses” to create materials

Create a scissor drape material with default values from LM\_Material ud\_t300\_n5208

### **3 Create the first ply**

Set angles to “0 0 0” to obtain default view

Create a scissor drape ply with start point in the middle of the surface, the reference direction in the global X-direction, reference angle zero, covering the entire surface

*Note that shear strain increases away from the starting point and the principal axes, which are geodesic lines by default*

Use the graphics control form to plot and hide the draped pattern, element angles, flat pattern, maximum strain value and starting point. Note the maximum shear angle of 14 degrees.

### **4 Create the second ply**

Change the reference angle to 30 degrees and create another scissor drape ply

*Note that this results in lower shear, 9 degrees.*

*Also, change in ply orientations is not necessarily equal to 30 degrees on individual elements, as a consequence of the nonlinearity of the draping process*

### **5 Create the third ply**

Change the starting point to the middle of the lower edge (e.g. node 11) and create another scissor draped ply

*Note the increased shear due to greater distances from the start point, maximum 30 degrees.*

### **6 Investigate the function of step length**

Change the step length to Implicit 2 (set in Additional Controls, Geometry) and create another similar scissor draped ply.

The default step length is calculated as a function of the area of the surface of the model. This multiplies the default step length by 2

Change the step length to Explicit, 2 (set in Additional Controls, Geometry) and create another scissor draped ply

This changes the step length to exactly 2 units

*Note that for small step lengths, the pattern may not cover the entire surface because the number of possible steps is limited due to limited (not unlimited!) computer resources.*

*If you have any difficulty with this exercise, examine or play the session file “drapeintro.ses” after opening a new database.*

MacNeal-Schwendler  
**Nordic AS**

Erling Wiig

*Laminate Modeler*  
*Course Exercises*

## LESSON 5

# *Draping with splits*

### What you will learn from this exercise

- 25 How splits are introduced in a ply
- 26 Capabilities and limitations using splits

## **1 Create the geometry**

*In the Goemetry menu*

Action: Create  
Object: Curve  
Method: 2DArc 2Angles  
Enable Patran2 convention  
Curves pr. arc: enter "3"  
Radius: enter "500"  
Start Angle: enter "0"  
End Angle: enter "90"

Action: Create  
Object: Surface  
Method: Revolve  
Enable Patran2 convention  
Axis: Coord 0.2  
Total Angle: enter "360"  
Surface pr Curve: enter "8"  
Curve List: Pick curve 1:3

## **2 Create the mesh**

*In the Finite Elements Menu*

Action: Create  
Object: Mesh  
Methods: Surface  
Global Edge Length: enter "50"  
Element Topology: select "Quad4"  
Mesher: Select "Paver"  
Surface List: select "Surface 1:24"

*Do not bother with the mesh quality for this exercise*

Action: Equivalence

Object: Nodes  
Method: Tolerance Qube  
Tolerance Cube: enter “0.01”

### **3 Create the materials**

Play session file “materials.ses” to input the material  
Create a LM\_Material based on “ud\_t300-n5208” with default values

### **4 Create the plies**

View the model from above (Angles 90,0,0)  
Set Step Length to Explicit 25. Create A Scissor Drap with starting point in the centre covering all the surfaces. Reference Direction along the global X-axis, Reference Angle 0.

Note that the maximum shear angle is 50 degrees! This is not usable for any real world application.

Do another similar drap with Reference Angle 45 degrees. Note no changes in shear (of course).

### **5 Introduce Cuts**

Introduce four cuts. This is done under Additional Controls, Boundaries, Define Splits.

Add the lower four curves where the shear is excessive to the split application region.

Remake the drap (keep 45 degrees Ref angle)

Maximum shear is now reduced to 43 degrees. This is better than our last try, but still too much.

## **6 Refine Cuts**

Extend the cuts by adding the next four curves and redrape using the same inputs. The maximum shear angle is now 35 degrees. This is still not good, but we will keep it for this exercise. In fact the only solution to our problem is to drape smaller sections of the sphere.

## **7 Make a new drape**

Now redefine the cuts to the other 8 lines in a similar fashion and redrape with an Reference Angle of 0 degrees. This drape is exactly the same other than being rotated 45 degrees about the global y-axis

## **8 Make the layup**

Note that you can use the Show, LM\_Ply, Graphics to browse through the existing plies to see which to choose when making the layup.

Create a layup with the last two plies explained in this exercise. Stack them in a A/B/A/B fashion until the total number of layers is 16.

## **9 Make boundary- and loading conditions**

Create an displacement restriction of “<,0,>” for the translations applicable for all the lines in the bottom of the sphere.

Create another displacement restriction of “<0,0,0> for the translations and “<0,0,0>” for the rotations for on point anywhere on the sphere lower edge.

Add an internal pressure on all surfaces of 1 (MPa)

## **10 Do the analysis**

Run the analysis and read the results

MacNeal-Schwendler  
**Nordic AS**

Erling Wiig

*Laminate Modeler*  
*Course Exercises*

## **11 Postprocess**

Look at the displacements in the y-direction.  
Explain what you see!

MacNeal-Schwendler  
**Nordic AS**

Erling Wiig

*Laminate Modeler*  
*Course Exercises*

## LESSON 6

# *Springback analysis of a jet engine cowling*

### What you will learn from this exercise

- 27 Importance of springback, and the need to correct for it
- 28 Thermal induced deflections on a composite model

### **1 Make the model**

Create a new database springback.db

Play session file “springback\_geom.ses” to generate geometry

### **2 Make the material**

Play session file “materials.ses” to create materials

Create a laminate material using “ud\_t300\_n5208” properties and a thickness of 0.25 (mm)

### **3 Make the plies**

Create a ply with origin [1250 0 1250] and initial vector along the global x-axis

Create similar plies, but with different reference angles: 45, 90 and 135 degrees.

### **4 Make the layup**

Create a layup with the 0,45,90,135 plies stacked six times (giving a 24 ply layup)

### **5 Specify the boundary conditions**

Fix lower edge in translation and rotation

Create a nodal temperature load of -55 over the whole body

MacNeal-Schwendler  
**Nordic AS**

Erling Wiig

*Laminate Modeler*  
*Course Exercises*

## **6 Analyse the model**

Analyse the model, and read in the results

You now simulate what happens when the material cools from curing temperature to room temperature. Because of the orthotropic thermal and mechanical properties the model distorts. This yields a different model shape than the one we made in the mould. Obviously we will have to correct for this in a way such as the deformed shape is the one we want!

## **7 Verify the results**

Plot the thermal induced deformation of the model

*If you have any difficulty with this exercise, examine or play the session file “springback.ses” after opening a new database.*
